

REMARKS

Reconsideration of the present application is respectfully requested. Claim 1 has been amended. Claim 25 has been previously canceled. No claims have been added. No new matter has been added. **Applicants hereby respectfully request a telephone interview with the Examiner to be held before the Examiner's issuance of an office action in response to this amendment.**

Claim Rejections

Independent claims 1, 5, 6, 11, 12, 17, 18, 23 and 24 stand rejected under 35 U.S.C. § 103(a) based on Lewis (U.S. Patent no. 6,378,066). Applicants respectfully traverse the rejections.

As explained in the Request for Continued Examination (the RCE) mailed on 7/21/2006, the present invention generally relates to a method for scheduling tasks in a multiprocessor system and providing parallel or concurrent execution of those tasks while implicitly synchronizing access to resources used by that system. In one embodiment of the present invention, scheduling domains are used for scheduling tasks. At least one scheduling domain is associated with at least two tasks and a resource, such as a data structure, shared by the at least two tasks. Implicit synchronization is achieved by prohibiting tasks associated with one scheduling domain from running in parallel or concurrently. With the above remarks in mind, attention is directed to independent claim 1 of the present invention.

Claim 1 recites:

1. A computer implemented method including
scheduling tasks from a set thereof for running on a plurality of processors, wherein each task of the set of tasks is associated with one of a plurality of scheduling domains, **at least one scheduling domain being associated with at least two tasks of the set of tasks and a resource shared by the at least two tasks, and wherein tasks within each scheduling domain can be run on different processors but are prohibited from running concurrently even if run on different processors;** and
allowing a plurality of tasks of the set of tasks to run concurrently in different scheduling domains.
(Emphasis added).

In contrast, Lewis does not teach or suggest the above emphasized claim limitation. As explained in the RCE, Lewis discloses a method of solving data dependency problems among a number of tasks. As discussed in Lewis's abstract, lines 50-57 of column 5, and line 66 of column 5 through line 3 of column 36, Lewis discloses dividing a memory region into a number of blocks, each block storing data needed for solving a problem. For each block, a program code is specified to be executed on the values within the block. Dependencies among the blocks are specified for scheduling the processing order of these blocks. If a first block is dependent on a second block, the second block must be processed before the first block may be processed. For example, assume block 1 is associated with code 1, block 2 is associated with code 2 and block 1 is dependent on block 2. Then, according to Lewis' disclosure, block 2 is processed by code 2 before block 1 may be processed by code 1. Lewis, however, does not teach or suggest a method solving the problem of synchronizing two tasks sharing a same resource, much less teaching or suggesting a scheduling domain associated with at least two tasks and a resource shared by the at least two tasks for implicitly synchronizing the at least two tasks with respect to the shared resource.

The Examiner, however, alleges that Lewis's figures 8, 9, 10A and 10B and column 5, lines 50-55 disclose that blocks with the same program code are said to share the same "state". Thus, the Examiner is essentially arguing that these blocks are sharing the same resource, the program code; therefore, these blocks and the program code shared by these blocks allegedly read on the claim limitation of a scheduling domain associated with at least two tasks and a resource shared by the at least two tasks. However, Lewis's column 5, lines 55-57 further states that these blocks can generally be executed in parallel because they do not depend on one another for results. In contrast, claim 1 recites "wherein tasks within each scheduling domain can be run on different processors but are prohibited from running concurrently even if run on different processors." Thus, rather than teach or suggest at least one scheduling domain being associated with at least two tasks of the set of tasks and a resource shared by the at least two tasks, and wherein tasks within each scheduling domain can be run on different processors but

are prohibited from running concurrently even if run on different processors, the cited section of Lewis teaches away from the above emphasized limitation.

Thus, at least for the foregoing reasons, Lewis does not teach or suggest each and every limitation of claim 1. Therefore, claim 1 is not rendered obvious in view of Lewis. Claim 1 and all claims which depend on it are patentable over Lewis.

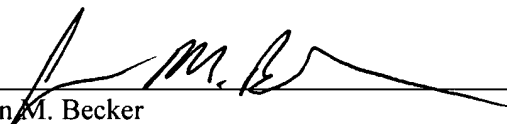

All other independent claims each recite essentially similar limitation as discussed above for claim 1. Thus, these other independent claims and all claims which depend on them are also patentable over Lewis.

For the foregoing reasons, the present application is believed to be in condition for allowance, and such action is earnestly requested.
